## What is Zolpidem?

Zolpidem is a hypnotic medication primarily prescribed for short-term treatment of insomnia. It belongs to the class of drugs known as non-benzodiazepine sedative-hypnotics or "Z-drugs." It works by interacting selectively with the gamma-aminobutyric acid type A (GABA<sub>A</sub>) receptors in the brain, especially at the benzodiazepine site, to enhance the calming effect of GABA. This induces sedation and helps facilitate the onset and maintenance of sleep.

## Uses

- Short-term management of insomnia characterized by difficulties with sleep initiation or maintenance
- Occasionally prescribed off-label for other sleep disorders and neurological conditions under medical supervision.

## How Does Zolpidem Work?

Zolpidem binds selectively to GABA<sub>A</sub> receptors containing the  $\alpha 1$  subunit, enhancing GABAergic inhibition in the central nervous system. This modulation

increases chloride ion influx into neurons, hyperpolarizing them and reducing neuronal excitability, leading to sedation and sleep induction.
