## What is Alprazolam?

Alprazolam is a benzodiazepine medication used to treat anxiety disorders, panic attacks, and stress-related conditions. It works by enhancing the effect of GABA (gamma-aminobutyric acid), an inhibitory neurotransmitter in the brain that helps reduce excessive brain activity, leading to a calming effect. Alprazolam is classified as a Schedule IV controlled substance because it has a legitimate medical use but requires careful medical supervision.

When used responsibly, Alprazolam can provide fast relief from acute anxiety and panic episodes, helping improve overall mental stability. Misuse, however, can lead to dependency, so proper dosage and monitoring are essential.
